### Serial Data Interface

To enhance the flexibility and function of the clock synthesizer, a two-signal serial interface is provided. Through the Serial Data Interface, various device functions, such as individual clock output buffers are individually enabled or disabled. The registers associated with the Serial Data Interface initialize to their default setting at power-up. The use of this interface is optional. Clock device register changes are normally made at system initialization, if any are required. The interface cannot be used during system operation for power management functions.

### Data Protocol

The clock driver serial protocol accepts byte write, byte read, block write, and block read operations from the controller. For block write/read operation, access the bytes in sequential order from lowest to highest (most significant bit first) with the ability to stop after any complete byte is transferred. For byte write and byte read operations, the system controller can access individually indexed bytes. The offset of the indexed byte is encoded in the command code described in *Table 1*.

The block write and block read protocol is outlined in *Table 2* while *Table 3* outlines byte write and byte read protocol. The slave receiver address is 11010010 (D2h).

**Input Pins Clarification**

**SRC\_EN Clarification**

SRC\_EN pin is a 3.3V active high input pin. When the SRC\_EN signal is a logic low, all SRC clocks will be disabled synchronously regardless of the CLKREQ# state. If SRC\_EN pin remains disabled it can be re-enabled through the SMBus register. The SRC\_EN signal will be asserted high whenever the SRC\_EN pin or the SRC\_EN bit is a logic high.

**CLKREQ# Clarification**

The CLKREQ# signals are active low inputs used to cleanly enable and disable selected SRC outputs. If CLKREQ# pin remains disabled it can be re-enabled through the SMBus register. The CLKREQ# signal will be asserted high whenever the CLKREQ# pin or the CLKREQ# bit is a logic high.

**OE Clarification**

The OE signals are active high inputs used to enable and disable single-ended outputs. If OE pin remains disabled it can be re-enabled through the SMBus register. The OE signal will be asserted high whenever the OE pin or the OE bit is a logic high. OE pins is required to be driven at all time.

**RESET# Clarification**

The RESET# signal is 3.3V output signal with an internal 100k-ohm pull-down. The RESET# output is low during power up. When SRC\_EN is low and after all SRC clocks go low, RESET# will go low. If any of the SRCs is running when SRC\_EN is low, RESET# will not go low. When PD pin is de-asserted and SRC\_EN goes high, RESET# will remain low for 100ms then goes high. If PD is asserted, RESET# will be low.
